ping -R

Wie ermittelt der Befehl ping die Route von ktdsp32 zu ktdsap1.local.

Der Befehl ping zeichnet mit der Option **-R** die Route des Paketes auf. Die Option **-c2** bricht ping nach 2 Durchläufen ab und gibt das Ergebnis aus. Der Aufruf in einer Konsole liefert folgendes Ergebnis.

```
ktdsp32:~ # ping -R ktdsap1.local -c2
PING ktdsap1.local (10.40.20.11) 56(124) bytes of data.
64 bytes from 10.40.20.11: icmp_req=1 ttl=62 time=4.08 ms
RR:    ktdsp32.local (10.20.23.32)
       ktdsrt1.local (10.23.5.61)
       ktdsrt3-40.local (10.40.0.1)
       10.40.20.11
       10.40.20.11
       ktdsrt3.local (10.23.5.63)
       ktdsrt1-20.local (10.20.0.1)
       ktdsp32.local (10.20.23.32)

64 bytes from 10.40.20.11: icmp_req=2 ttl=62 time=3.52 ms      (same route)

--- ktdsap1.local ping statistics ---
2 packets transmitted, 2 received, 0% packet loss, time 1001ms
rtt min/avg/max/mdev = 3.528/3.806/4.084/0.278 ms
ktdsp32:~ #
```

Was hat der Aufruf des ping Befehls bewirkt?

Als erstes wurde der Name **ktdsap1.local** vom DNS Server aufgelöst. Dazu wurde eine DNS Anfrage (s. Paket No. 23) an der Nameserver gesendet. Dieser schickt als Antwort (s. Paket No. 24) die IP **10.40.20.11** zurück.

```
ktdsp32:~ # host ktdsap1
ktdsap1.local has address 10.40.20.11
```

Nun kann das System den **Echo (ping) request** (s. Paket No. 25) senden und erhält eine Antwort (s. Paket No. 26) als **Echo (ping) reply**.

Da in der Ausgabe in der Konsole nicht nur die IP Adressen sondern auch die Namen ausgegeben werden muss zu jeder gespeicherten IP eine DNS Anfrage (s. Paket No. 27 bis 42 mit der dazugehörigen Antwort) getätigert werden.

Danach versendet das System den zweiten **Echo (ping) request** (s. Paket No. 43f). *Nicht bekannte Namen* zu IP Adressen werden erneut angefragt (s. Paket No. 45f: zu IP 10.40.20.11).

```
ktdsp32:~ # host 10.40.20.11
Host 11.20.40.10.in-addr.arpa. not found: 3(NXDOMAIN)
```

Grund für die nicht Auflösung der IP ist ein **Zahlendreher** in der zugehörigen Zonendatei (s.u. **20.11 ≠ 11.20**).

```
$TTL 2D
40.10.in-addr.arpa.      IN SOA ktdss01.local. root.localhost. (
                           2011100501      ; serial
                           1D              ; refresh
                           2H              ; retry
                           1W              ; expiry
                           2D )            ; minimum

                           IN NS          ktdss01.local.
                           IN NS          ktdss02.local.
1.0     IN PTR          ktdsrt3-40.local.
20.11   IN PTR          ktdsap1.local.
```

Nach der Änderung muss auch die **Serienummer** der Zonendatei aktualisiert werden.

```
$TTL 2D
40.10.in-addr.arpa.      IN SOA ktdss01.local. root.localhost. (
                           201111001      ; serial
...
11.20   IN PTR          ktdsap1.local.
```

Nun führrt die DNS Anfrage zum gewünschten Ergebnis.

```
ktdsp32:~ # host 10.40.20.11
11.20.40.10.in-addr.arpa domain name pointer ktdsap1.local.
```

```
ktdsp32:~ # ping -R ktdsap1.local -c2
PING ktdsap1.local (10.40.20.11) 56(124) bytes of data.
64 bytes from ktdsap1.local (10.40.20.11): icmp_req=1 ttl=62 time=4.05 ms
